<u>Document Factory Proof of Concept</u>

<u>Intention:</u>
In order to have a working version of the Document Factory, we would like to start with a simple easy POC that will be used by potential clients and feedback will be steered to words a final analysis of the final document factory.

<u>Scope:</u>
Create a basic integration of the **Grapesjs.com** plugin into a simple workflow so it can be used to generate document templates.

1) Start with a simply based login page, when login is correct the **grapejs.com** application will start. The user will work and create the document, at the end the user will export the result. The export is saved in a zip file and is basically an HTML result.
2) Create a list (overview) of templates that the user has created. provide a link to open the template. When clicked the template opens.
3) The open template will be filled by the user and then he has the option to save it in pdf format.
4) The list (item 2) contains an overview of the saved pdf files.

<u>Architecture:</u>
We have not decided yet what would be the best way to use this as your experience can decide it.
We have a Linux server who already has a small app running or add it for the poc on our crystalstick.beer. Or should we compile it on to a version to install it independently on each workstation?

The Linux server (only access via Putty)
IP: 185.104.30.16
